Consider the equation $Y = X + \varepsilon$ in which:

- 1 Y is the observed random vector;
- 2 X is the latent random vector;
- 3 ε is a random noise vector.

Standing assumptions:

- (A1) X and ε are independent;
- (A2) Y , X and ε have densities with respect to the Lebesgue measure, denoted respectively by g, f and γ ;
- (A3) both f and g belong to $L^1(\mathbb{R}^d) \cap L^2(\mathbb{R}^d)$.

Consider the equation $Y = X + \varepsilon$ in which:

- 1 Y is the observed random vector;
- 2 X is the latent random vector;
- 3 ε is a random noise vector.

Standing assumptions:

- (A1) X and ε are independent;
- (A2) Y , X and ε have densities with respect to the Lebesgue measure, denoted respectively by g , f and γ ;
- (A3) both f and g belong to $L^1(\mathbb{R}^d) \cap L^2(\mathbb{R}^d)$.

The density f then satisfies the equation $T_\gamma f = g$, in which T_γ is the convolution operator

$$\begin{aligned} T_\gamma: \quad L^2(\mathbb{R}) &\longrightarrow L^2(\mathbb{R}) \\ f &\longmapsto T_\gamma f := f * \gamma. \end{aligned}$$

Let's mention a well-known approximation theorem:

Theorem

Let $\varphi \in L^1(\mathbb{R}^n)$ be such that $\int \varphi(x) dx = 1$. For every $\beta > 0$, let

$$\varphi_\beta(x) := \frac{1}{\beta^n} \varphi\left(\frac{x}{\beta}\right)$$

Let $p \in [1, \infty)$. Then, for every $f \in L^p(\mathbb{R}^n)$,

$$\|\varphi_\beta * f - f\|_p \longrightarrow 0 \quad \text{as} \quad \beta \downarrow 0$$

Consider the inverse problem $Tf = g$ in which $T: L^2(\mathbb{R}^n) \rightarrow L^2(\mathbb{R}^n)$ has unbounded pseudo-inverse as usual.

Consider the inverse problem $Tf = g$ in which $T: L^2(\mathbb{R}^n) \rightarrow L^2(\mathbb{R}^n)$ has unbounded pseudo-inverse as usual.

Definition

A function $\psi_\beta: \mathbb{R}^n \times \mathbb{R}^n \rightarrow \mathbb{R}$ is called a *mollifier* if

- (1) for every $\beta > 0$ and $\mathbf{y} \in \mathbb{R}^n$, $\psi_\beta(\cdot, \mathbf{y}) \in L^1(\mathbb{R}^n) \cap L^2(\mathbb{R}^n)$, and

$$\int_{\mathbb{R}^n} \psi_\beta(\mathbf{x}, \mathbf{y}) \, d\mathbf{x} = 1$$

- (2) for every $f \in L^2(\mathbb{R}^n)$, the function f_β defined by

$$f_\beta(\mathbf{y}) = \langle f, \psi_\beta(\cdot, \mathbf{y}) \rangle = \int_{\mathbb{R}^n} f(\mathbf{x}) \psi_\beta(\mathbf{x}, \mathbf{y}) \, d\mathbf{x}$$

converges to f in $L^2(\mathbb{R}^n)$ as $\beta \downarrow 0$

Now, assuming the existence of a family of functions $(v_\beta(\cdot, \mathbf{y}))$ such that

$$\forall \beta > 0, \quad \forall \mathbf{y} \in \mathbb{R}^n, \quad T^* v_\beta(\cdot, \mathbf{y}) = \psi_\beta(\cdot, \mathbf{y}) \quad (1)$$

we see that f_β is then given by

$$f_\beta(\mathbf{y}) = \langle f, T^* v_\beta(\cdot, \mathbf{y}) \rangle = \langle Tf, v_\beta(\cdot, \mathbf{y}) \rangle = \langle g, v_\beta(\cdot, \mathbf{y}) \rangle$$

Now, assuming the existence of a family of functions $(v_\beta(\cdot, \mathbf{y}))$ such that

$$\forall \beta > 0, \quad \forall \mathbf{y} \in \mathbb{R}^n, \quad T^* v_\beta(\cdot, \mathbf{y}) = \psi_\beta(\cdot, \mathbf{y}) \quad (1)$$

we see that f_β is then given by

$$f_\beta(\mathbf{y}) = \langle f, T^* v_\beta(\cdot, \mathbf{y}) \rangle = \langle Tf, v_\beta(\cdot, \mathbf{y}) \rangle = \langle g, v_\beta(\cdot, \mathbf{y}) \rangle$$

More generally, if $\psi_\beta(\cdot, \mathbf{y})$ belongs to $\mathcal{D}((T^*)^\dagger) = \text{ran } T^* + (\text{ran } T^*)^\perp$, then the minimum norm least square solution to (1) is used instead, and denoted by $v_\beta(\cdot, \mathbf{y})$ again.

Now, assuming the existence of a family of functions $(v_\beta(\cdot, \mathbf{y}))$ such that

$$\forall \beta > 0, \quad \forall \mathbf{y} \in \mathbb{R}^n, \quad T^* v_\beta(\cdot, \mathbf{y}) = \psi_\beta(\cdot, \mathbf{y}) \quad (1)$$

we see that f_β is then given by

$$f_\beta(\mathbf{y}) = \langle f, T^* v_\beta(\cdot, \mathbf{y}) \rangle = \langle Tf, v_\beta(\cdot, \mathbf{y}) \rangle = \langle g, v_\beta(\cdot, \mathbf{y}) \rangle$$

More generally, if $\psi_\beta(\cdot, \mathbf{y})$ belongs to $\mathcal{D}((T^*)^\dagger) = \text{ran } T^* + (\text{ran } T^*)^\perp$, then the minimum norm least square solution to (1) is used instead, and denoted by $v_\beta(\cdot, \mathbf{y})$ again. The family of mappings

$$\begin{aligned} \tilde{R}_\beta: \quad L^2(\mathbb{R}^n) &\longrightarrow L^2(\mathbb{R}^n) \\ g &\longmapsto \langle g, v_\beta(\cdot, \mathbf{y}) \rangle \end{aligned}$$

is then called an *approximate inverse* of T

Theorem (Consistency)

Assume g_n is a consistent nonparametric estimator of g , that is, that $E\|g_n - g\|$ goes to zero as n goes to infinity. Let $f_{\beta,n}$ denote the mollified solution corresponding to data g_n . There then exist a sequence $\beta_n \downarrow 0$ such that

$$E\|f_{\beta_n,n} - f_\circ\| \longrightarrow 0 \quad \text{as} \quad n \rightarrow \infty.$$
